PHP Tutorial

What is PHP?

- PHP == 'PHP: Hypertext Preprocessor' (recursive backronym)
- Open-source, server-side scripting language
- Used to generate dynamic web-pages
- PHP scripts reside between reserved PHP tags
- This allows the programmer to embed PHP scripts within HTML pages

History of PHP

- PHP began in 1995 when Rasmus Lerdorf developed a Perl/CGI script toolset he called the Personal Home Page or PHP
- PHP 2 released 1997 (PHP now stands for Hypertex Processor).
 Lerdorf developed it further, using C instead
- PHP 3 released in 1998 (50,000 users)
- PHP 4 released in 2000 (3.6 million domains). Considered debut of functional language and including Perl parsing, with other major features
- PHP 5.0.0 released July 13, 2004 (113 libraries>1,000 functions with extensive object-oriented programming)
- PHP 5.6.31 released July 6, 2017
- PHP 7.0 released December 2015
- Documentation available at: http://www.php.net/docs.php
- PHP 7.1 current "stable" release

What is PHP (cont'd)

- Interpreted language, scripts are parsed at run-time rather than compiled beforehand
- Executed on the server-side
- Source-code not visible by client: e.g. 'View Source' in browsers does not display the PHP code
- Various built-in functions allow for fast development
- Compatible with many popular databases
- Provides
 - + SAPI, Server Application Programming Interface (Direct Module)
 - + ISAPI, The Internet Server Application Programming Interface (IIS)
 - + CGI interface
 - + CLI (Command Line Interface)

What does PHP code look like?

- Structurally similar to C/C++
- Supports procedural and object-oriented paradigm (to some degree)
- All PHP statements end with a semi-colon
- Each PHP script must be enclosed in the reserved PHP tag

A Simple Example

Save as sample.php:

```
<!- sample.php -->
<html><body>
<strong>Hello World!</strong><br />
     <?php
        echo "<h2>Hello, World</h2>";
     ?>
                                       🥙 Mozilla Firefox
                                          Edit View History Bookmarks Tools Help
     <?php
                                          $myvar = "Hello World";
                                        http://www-scf.usc.ed...x/translated/test.php 🕇
     echo $myvar;
                                       Hello World!
     ?>
                                       Hello, World
</body></html>
                                       Hello World
```

Comments in PHP

• Standard C, C++, and shell comment symbols

```
// C++ and Java-style comment

# Shell-style comments

/* C-style comments
    These can span multiple lines */
```

Variables in PHP

- PHP variables must begin with a "\$" sign
- The variable name must be followed by a letter or underscore
- Case-sensitive (\$Foo != \$fOo)
- Static, Global and locally-scoped variables
 - + Global variables can be used anywhere (declared outside a function)
 - + Local variables restricted to a function or class
 - + Variable declared "static" do not disappear when a function is completed
- Certain variable names reserved by PHP. Examples:
 - + Form variables (\$_POST, \$_GET)
 - + Server variables (\$_SERVER)

PHP Variables

- Variables are not statically typed
- Integers can become floats, then can become strings
- Variables take the type of the current value
- Variable types include :
 - Boolean
 - Integer
 - Float
 - String
 - Array
 - Object
 - Resource
 - NULL

PHP Variables

Assigned by value

```
$foo = "Bob"; $bar = $foo;
```

Assigned by reference, this links vars

```
$bar = &$foo;
```

- Some variables are pre-assigned, e.g. server and env vars
- For example, there are PHP vars
 - + PHP_SELF, a variable that returns the current script being executed, including its name and path (Ex: \$_SERVER['PHP_SELF'])
 - + \$HTTP_GET_VARS, an associative array of variables passed to the current script (deprecated by \$_GET)

Displaying Variables

 To display a variable with the echo statement, pass the variable name to the echo statement without enclosing it in quotation marks :

```
$VotingAge = 18;
echo $VotingAge;
```

 To display both text strings and variables, send them to the echo statement as individual arguments, separated by commas:

```
echo "The legal voting age is ", $VotingAge,
    ".";
```

Naming Variables

- The following rules and conventions must be followed when naming a variable:
 - Variable names must begin with a dollar sign (\$)
 - Variable names may contain uppercase and lowercase letters, numbers, or underscores (_). The first character after the dollar sign must be a letter or underscore.
 - Variable names cannot contain spaces
 - Variable names are case sensitive

PHP Constants

- Constants are special variables that cannot be changed
- Constant names do not begin with a dollar sign (\$)
- Start with letter or underscore (_) followed by letters, numbers or underscores
- Use them for named items that will not change
- Constant names use all uppercase letters
- Use the define() function to create a constant define("CONSTANT_NAME", value);
- The value you pass to the define() function can be a text string, number, or Boolean value
- Constants have global scope

PHP Operators

Standard Arithmetic operators

```
+, -, *, / and % (modulus)
```

• String concatenation with a period (.)

```
$car = "SEAT" . " Altea";
echo $car; would output "SEAT Altea"
```

- Basic Boolean comparison with "=="
- Using only = will overwrite a variable value
- Less than < and greater than >
- <= and >= as above but include equality

PHP Operators (cont'd)

Assignment (=) and combined assignment

Data Types

- PHP is **not** strictly typed
- PHP support 8 "primitive" types:
 - + 4 scalar types: boolean, integer, double (floating-point), string
 - + 2 compound types: array and object
 - + 2 special types; resource and null
- PHP decides what type a variable is
- PHP can use variables in an appropriate way automatically
- E.g.

```
$vat_rate = 0.175; /* VAT Rate is numeric */
echo $vat rate * 100 . "%"; //outputs "17.5%"
```

 \$vat_rate is converted to a string for the purpose of the echo statement

Numeric Data Types

- PHP supports two numeric data types:
 - An integer is a positive or negative number and 0 with no decimal places (-250, 2, 100, 10,000)
 - A floating-point number (double) is a number that contains decimal places or that is written in exponential notation (-6.16, 3.17, 2.7541)

Boolean Values

- A Boolean value is a value of TRUE or FALSE
- It decides which part of a program should execute and which part should compare data
- In PHP programming, you can only use TRUE or FALSE Boolean values
- In other programming languages, you can use integers such as 1
 TRUE, 0 = FALSE

Variable usage

echo example

- Notice how echo '5x5=\$foo' outputs \$foo rather than replacing it with
 25
- Strings in single quotes ('') are not interpreted or evaluated by PHP
- This is true for both variables and character escape-sequences (such as "\n" or "\\")

Arithmetic Operations

```
<?php
     $a=15;
     $b=30;
     $total=$a+$b;
     Print $total;
     Print "<p><h1>$total</h1>";
     // total is 45
?>
```

Concatenation

Use a period to join strings into one.

```
<?php
$string1="Hello";
$string2="PHP";
$string3=$string1 . " " . $string2;
Print $string3;
?>
```

```
Hello PHP
```

Escaping the Character

• If the string has a set of double quotation marks that must remain visible, use the \ [backslash] before the quotation marks to ignore and display them.

```
<?php
$heading="\"Computer Science\"";
Print $heading;
?>
```

```
"Computer Science"
```

PHP Control Structures

- Control Structures: the structures within a language that allow us to control the flow of execution through a program or script.
- Grouped into conditional / branching structures (e.g. if/else) and repetition structures (e.g. while loops).
- Example if/else if/else statement:

```
if ($foo == 0) {
    echo 'The variable foo is equal to 0';
}
else if (($foo > 0) && ($foo <= 5)) {
    echo 'The variable foo is between 1 and 5';
}
else {
    echo 'The variable foo is equal to '.$foo;
}</pre>
```

If ... Else...

```
If (condition)
{
         Statements;
}
Else
{
         Statement;
}
```

```
<?php
If($user=="John")
{
         Print "Hello John.";
}
Else
{
         Print "You are not John.";
}
?>
```

No 'Then' in PHP!

While Loops

```
<?php
$count=0;
While($count<3)
{
         Print "hello PHP. ";
         $count += 1;
         // $count = $count + 1;
         // or
         // $count++;
}
?>
```

hello PHP. hello PHP. hello PHP.

Date Display

```
$datedisplay=date("yyyy/m/d");
Print $datedisplay;
                                       2012/4/1
# If the date is April 1st, 2012
# It would display as 2012/4/1
$datedisplay=date("1, F j, Y"); (see next slide for symbol
meanings)
                                 Wednesday, April 1, 2012
Print $datedisplay;
# If the date is April 1st, 2012
# Wednesday, April 1, 2012
```

Month, Day & Date Format Symbols

M	Jan
F	January
m	01
n	1

Day of Month	d	01
Day of Month	j	1
Day of Week		Monday
Day of Week	D	Mon

Functions

- Functions MUST be defined before they can be called
- Function headers are of the format

```
function functionName($arg_1, $arg_2, ..., $arg_n)
```

- + Note that no return type is specified
- Unlike variables, function names are not case sensitive

```
(foo(...) == Foo(...) == FoO(...)
```

Functions example

```
<?php
    // This is a function
   function foo($arg_1, $arg_2)
     $arg_2 = $arg_1 * $arg_2;
     return $arg_2;
    result_1 = foo(12, 3);
                               // Store the function
   echo $result_1;
                                // Outputs 36
   echo foo(12, 3);
                                // Outputs 36
?>
```

Include Files

Include "footer.php" by placing within the HTML the line

```
<?php include 'footer.php'; ?>
```

The file footer.php might look like:

```
<hr SIZE=11 NOSHADE WIDTH="100%">
<i>Copyright © 2010-2012 USC </i></font><br><i>ALL RIGHTS RESERVED</i></font><br><i>URL: http://www.usc.edu</i></font><br>
```

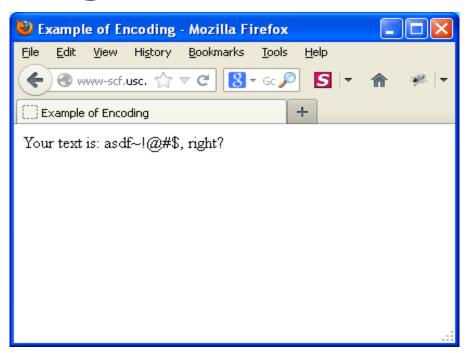

Some simple examples

These examples can be found at

http://cs-server.usc.edu:45678/examples/php/php_ex/translated/index.html

Example – Encoding Form Data

before after

Example – Encoding Form Data Script

```
<HTML>
<HEAD><TITLE>Example of Encoding</TITLE></HEAD>
<BODY>
<?php if($ POST["submit"]): ?>
        Your text is: <?php echo $ POST["input"]; ?>, right?
<?php else: ?>
        <H1>Please enter some text</H1>
        <FORM ACTION="" METHOD=POST>
        Enter text: <INPUT NAME=input><BR>
        <INPUT TYPE=submit name="submit">
        <INPUT TYPE=reset></form>
<?php endif; ?>
</BODY>
</HTML>
• Note: PHP 5.4+ warns if not doing this: if (isset($_POST["submit"])
```

Example – Displaying a Text File

This php program is invoked by clicking on the link Example – Displaying a text file

Resulting Output

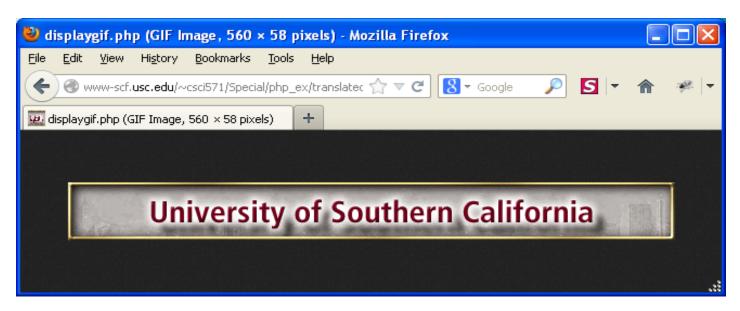

Example – Source of displayfile.php Script

```
<?php
$ourFileName = "apple.txt";
$ourFileHandle = fopen($ourFileName, "r") or die("can't open file");
$file = fread($ourFileHandle, filesize($ourFileName));
fclose($ourFileHandle);
header("Content-type: text/plain");
echo $file;
?>
```

Example – Returning a GIF Image

This program is also invoked by clicking on a link

 Example – Returning a GIF Image

Resulting Output

Example – Source for displaygif.php Script

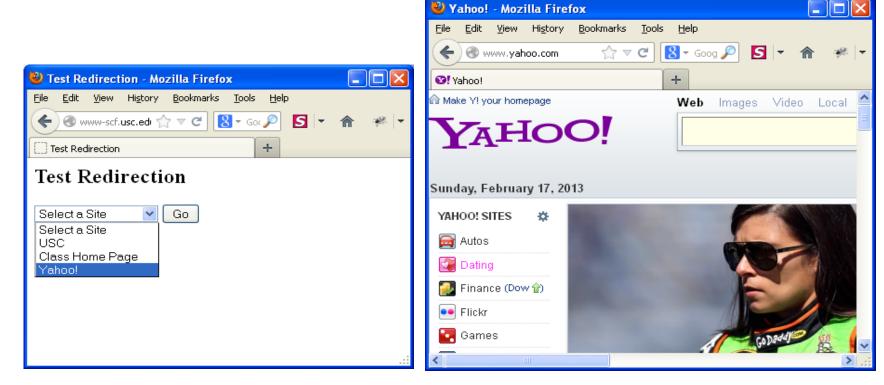

```
<?php
$ourFileName = "BanS_USC.gif";
$ourFileHandle = fopen($ourFileName, "r") or die("can't open file");
$file = fread($ourFileHandle, filesize($ourFileName));
fclose($ourFileHandle);
header("Content-type: image/gif");
echo $file;
?>
```

Example – Redirection in php

This program is also invoked by clicking on a link

Yahoo! - Mozilla Firefox

Example - Redirection

Before After

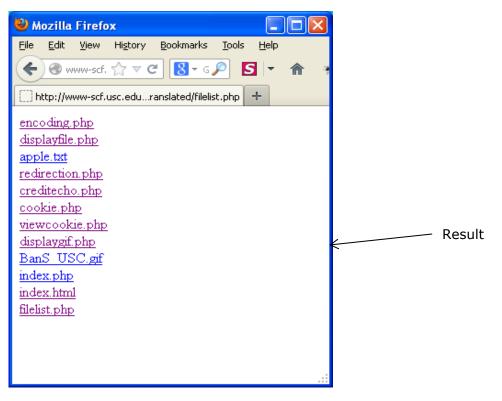

Example – redirection.php Script

```
<?php if($ POST["submit"]): ?>
<?php header("Location: $_POST[url]"); ?>
<?php else: ?>
<html><head><title>Test Redirection</title></head>
<body>
<h2>Test Redirection</h2>
<form method="post" action="">
<select name="url">
<option selected=selected value="">Select a Site</option>
<option value="http://www.usc.edu">USC</option>
<option value="http://www-scf.usc.edu/~csci571/index.html">Class Home
  Page</option>
<option value="http://www.yahoo.com">Yahoo!</option>
</select> <input type="submit" value="Go" name="submit">
</form></body></html>
<?php endif; ?>
```

Example - Creating a File List

This program is also invoked by clicking on a link

 Example – Creating a File List

Example – Source for filelist.php Script

```
<?php
//echo getcwd(); get current working directory
if ($handle = opendir('/home/scf-
  22/csci571/public html/Special/php ex/translated')) {
    while (false !== ($entry = readdir($handle))) {
                if ($entry != "." && $entry != "..") {
               echo "<a href='$entry'>$entry</a><br/>\n";
    closedir($handle);
?>
```

Simple counter example

This example is currently stored at: http://csci571.herokuapp.com/example_counter.php

Simple counter script

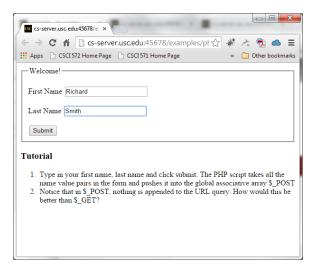

```
<?php
$ourFileName = "counter.txt";
$ourFileHandle = fopen($ourFileName, "r") or die("can't open file");
$num = fread($ourFileHandle, filesize($ourFileName));
fclose($ourFileHandle);
$ourFileHandle = fopen($ourFileName,"w") or die("can't open file");
$num++;
echo "<h1>Welcome Visitor #" . $num . "</h1>";
fwrite($ourFileHandle, $num);
fclose($ourFileHandle);
?>
<h3>Simple Counter PHP Example</h3>
<01>
The PHP script reads in the txt file and gets the current
  value.
Then, it increments that current value by 1, prints out the visitor
#, and writes it to the file.
```

PHP - Dealing with the client

- <form method="post" action="file.php" id="frmid" >
 - + Method specifies how the data will be sent
 - + Action specifies the file to go to. E.g., file.php
 - + id gives the form a unique name
- Post method sends all contents of a form with basically hidden headers (not easily visible to users)
- Get method sends all form input in the URL requested using name=value pairs separated by ampersands (&)
 - + E.g., process.php?name=trevor&number=345
 - + Is visible in the URL shown in the browser

PHP - Example Using POST

```
<?php
include once("inc.php");
if(isset($ POST["submit"])):
?>
<h3>Thanks for submitting!</h3>
<?php print array($ POST); ?>
<?php endif; ?>
<form method="POST" action="">
<fieldset>
     <leqend>Welcome!</leqend>
     <|abel for="first name">First Name</label>
<input type="text" name="first_name"</pre>
value="<?php echo isset($ POST["first name"]) ?</pre>
$ POST["first name"]: "" ?>">
     <|abel for="first_name">Last Name</label>
<input type="text" name="last_name" value="<?php echo
isset($ POST["last name"]) ? $ POST["last name"] : "" ?>">
     <input type="submit" name="submit" value="Submit">
</fieldset></form>
```

PHP - Dealing with the client

- Summary
 - + Form elements contain input elements
 - + Each input element has an id
 - + If a form is posted, the file stated as the action can use:

```
$_POST["inputid"]
```

+ If a form uses the get method:

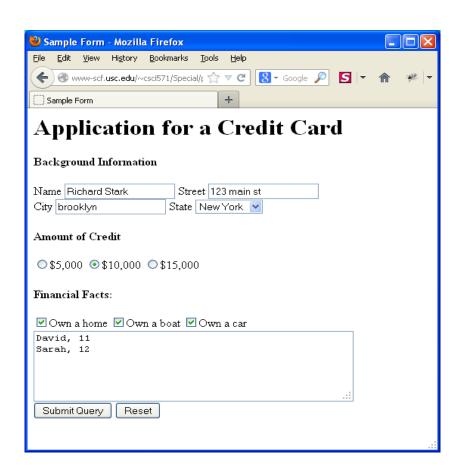

```
$_GET["inputid"]
```

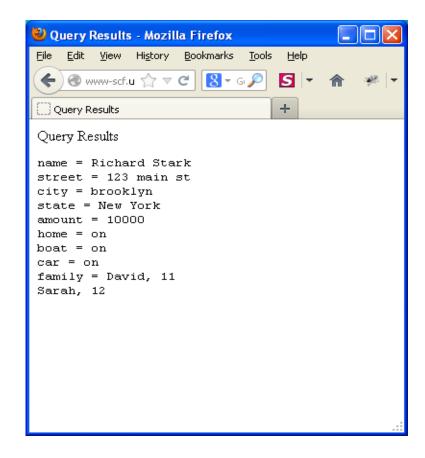

Ensure you set all id attributes for form elements and their contents

EXAMPLE - CGI Env. Access

```
<?php
     $env["REMOTE ADDR"] = getenv("REMOTE ADDR");
     $env["SERVER SOFTWARE"] = getenv("SERVER SOFTWARE");
     $env["SERVER NAME"] = getenv("SERVER NAME");
     $env["GATEWAY INTERFACE"] = getenv("GATEWAY INTERFACE");
     $env["SERVER PROTOCOL"] = getenv("SERVER PROTOCOL");
     $env["SERVER PORT"] = getenv("SERVER PORT");
     $env["REQUEST METHOD"] = getenv("REQUEST METHOD");
     $env["PATH INFO"] = getenv("PATH INFO");
     $env["PATH TRANSLATED"] = getenv("PATH TRANSLATED");
     $env["DOCUMENT ROOT"] = getenv("DOCUMENT ROOT");
     $env["SCRIPT NAME"] = getenv("SCRIPT NAME");
     $env["QUERY STRING"] = getenv("QUERY STRING");
     $env["REMOTE HOST"] = getenv("REMOTE HOST");
     $env["AUTH TYPE"] = getenv("AUTH TYPE");
     $env["REMOTE USER"] = getenv("REMOTE USER");
     $env["REMOTE IDENT"] = getenv("REMOTE IDENT");
     $env["CONTENT TYPE"] = getenv("CONTENT TYPE");
     $env["CONTENT LENGTH"] = getenv("CONTENT LENGTH");
     $env["HTTP ACCEPT"] = getenv("HTTP ACCEPT");
     $env["HTTP HOST"] = getenv("HTTP HOST");
     $env["HTTP USER AGENT"] = getenv("HTTP USER AGENT");
     $env["HTTP REFERER"] = getenv("HTTP REFERER");
     $env["HTTP REFERRER"] = getenv("HTTP REFFERER");
     print "";
     print "<caption>Environment Variables</caption>";
     while (list(\$key, \$val) = each(\$env)) {
       print "<b>$key</b><i>$val</i></t</pre>
   d>";
     print ""; }
```

Example – Echoing Inputs

Input Output

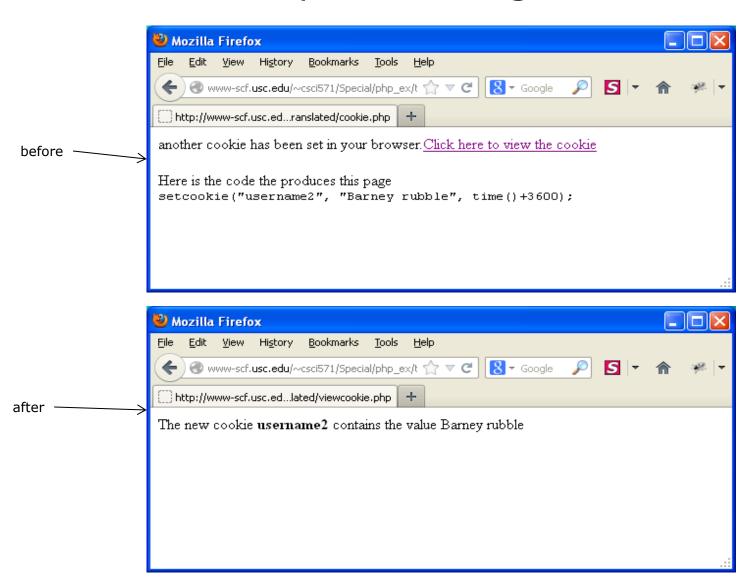

For the following slides, see "Translated PHP Examples from Perl":

http://cs-server.usc.edu:45678/examples/php/php_ex/translated/index.html

Example – Echoing Inputs Scripts

```
<?php if($ GET["submit"]): ?>
<HTML><HEAD><TITLE>Query Results/HEAD><BODY>
Query Results
<?php
foreach($ GET as $key => $value) {
        if ($key !== "submit") {
               echo key . " = " . value . "\n";
?>
</BODY></HTML>
<?php else: ?>
<HTML><HEAD><TITLE>Sample Form</TITLE></HEAD><BODY>
<H1>Application for a Credit Card</H1>
<FORM METHOD="GET" ACTION="">
<H4>Background Information</H4>
Name <INPUT name=name> Street <INPUT name=street><BR>
City <INPUT name=city> State <SELECT name=state>
<OPTION> Alabama <OPTION> California <OPTION> New York<OPTION> Wisconsin </SELECT>
<H4>Amount of Credit</H4> <INPUT type=radio name=amount value=5000>$5,000
<INPUT type=radio name=amount value=10000>$10,000
<INPUT type=radio name=amount value=15000>$15,000
<H4>Financial Facts:/H4> <INPUT type=checkbox name=home>Own a home
<INPUT type=checkbox name=boat>Own a boat
<INPUT type=checkbox name=car>Own a car<BR>
<TEXTAREA rows=5 cols=50 name=family>
Please describe here the names and ages of people in your family and the number of cards
you are requesting. </TEXTAREA>
<INPUT type=submit name="submit"> <INPUT type=reset></FORM></BODY>
</HTML>
<?php endif; ?>
```

Example - Setting a Cookie

Set / View cookie

```
Set cookie:
<?php
setcookie("username2", "Barney Rubble", time() + 3600 );
?>
View cookie:
<?php
if(isset($ COOKIE["username2"])) {
        echo "The new cookie <b>username2</b> contains the
  value " . $ COOKIE["username2"];
?>
```

Why PHP Sessions?

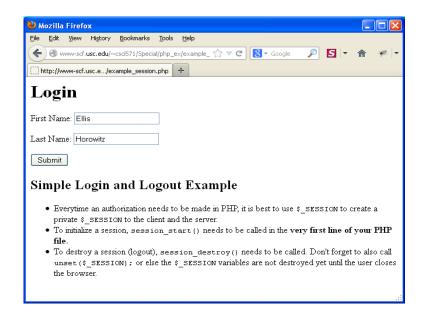

- Whenever you want to create a website that allows you to store and display information about a user, determine which user-groups a person belongs to, or utilize permissions on your website, PHP Sessions are vital to each of these features.
- PHP has a set of functions that can achieve the same results of Cookies without storing information on the user's computer. **PHP Sessions** store the information on the *web server* in a location that you chose in special files. These files are connected to the user's web browser via the server and a special ID called a "Session ID". This is virtually invisible to the user.

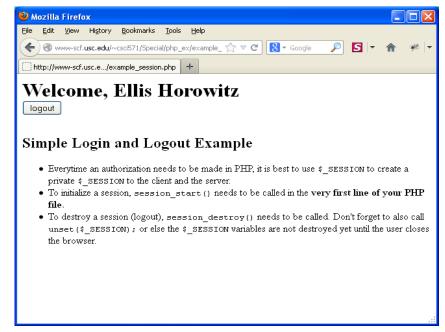

PHP Sessions

- Sessions store their identifier in a cookie in the client's browser
- Every page that uses session data must be preceded by the session_start() function
- Session variables are then set and retrieved by accessing the global \$_SESSION[]
- Sample session.php code:

```
<?php
    session_start();
    if (!$_SESSION["count"])
        $_SESSION["count"] = 0;
    if ($_GET["count"] == "yes")
        $_SESSION["count"] = $_SESSION["count"] + 1;
    echo "<h1>".$_SESSION["count"]."</h1>";
?>
<a href="session.php?count=yes">Click here to count</a>
```

EXAMPLE - SESSIONS

Initial Login Screen

Resulting Screen

\$_SESSION creates a private ID; session_start() and session_destroy()

example-session.php

```
<?php
       session start();
       if(isset($ POST["submit"])) {
               $ SESSION["fname"] = $ POST["fname"];
               $ SESSION["lname"] = $ POST["lname"];
       if(isset($ POST["logout"])) {
               session destroy();
               unset($ SESSION);
?>
<?php if(!(isset($ SESSION["fname"],$ SESSION["lname"]))): ?>
<h1>Login</h1>
<form method="POST">
<label for="username">First Name:</label>
       <input type="text" name="fname" />

       <label for="lname">Last Name:</label>
       <input type="text" name="lname" />
 <input type="submit" name="submit" value="Submit">
</form>
```

example-session.php (cont'd)

```
<?php else: ?>
<h1>Welcome, <?php echo ucwords($_SESSION["fname"] . " " . $_SESSION["lname"]);
?>
<form method="POST">
       <input type="submit" name="logout" value="logout">
</form>
<?php endif; ?>
<h2>Simple Login and Logout Example</h2>
<l
Everytime an authorization needs to be made in PHP, it is best to use
<code>$ SESSION</code> to create a private <code>$ SESSION</code> to the client
   and the server 
To initialize a session, <code>session start()</code> needs to be
called in the <b>very first line of your PHP file.</b>
To destroy a session (logout), <code>session destroy()</code> needs
to be called. Don't forget to also call <code>unset($ SESSION); </code> or else
the <code>$ SESSION</code> variables are not destroyed yet until the user closes
the browser.
</111>
```

Note: The ucwords() function converts the first character of each word in a string to uppercase.

Connecting to a Database

- PHP Has a set of functions that can be used with MySQL
- First step is to setup a link to the desired database
- See "MySQL Functions" docs at: http://php.net/manual/en/ref.mysql.php
- See MySQL API docs at: http://php.net/manual/en/book.mysql.php

```
$link = mysql_connect($host, $user, $password);
Mysql select db($database);
```

Making a Query

- Once a link is established, querying is easy
- Errors for any given function are returned by mysql_error()

```
$query = "SELECT * FROM $table;";
$result = mysql_query($query);
```

MySQL Result Set

- The value returned by mysql_query() is a reference to an internal data structure
- It can be parsed by various functions

```
$row = mysql_fetch_array($result);
$num_rows = mysql_num_rows($result);
$affected = mysql_affected_rows($result);
```

Associative Arrays

- An array that can be indexed by a string
- A set of key->value pairs
- Very similar to a hash in Perl

```
$row['id'] = $id;
$row = array('id' => $id);
echo $row['id'];
```

PHP foreach

- Similar to the Perl equivalent
- Allows iterating through each element of an array

```
foreach($arr as $item) {}
foreach($row as $key=>$value) {}
```

Put it All Together

```
<html><body>
<?php
  // setup a query
  $link = mysql_connect($host, $user, $password);
  mysql_select_db($database);
  $query = "SELECT * FROM $table WHERE id = '$id';";
  $result = mysql_query($query);
>
```

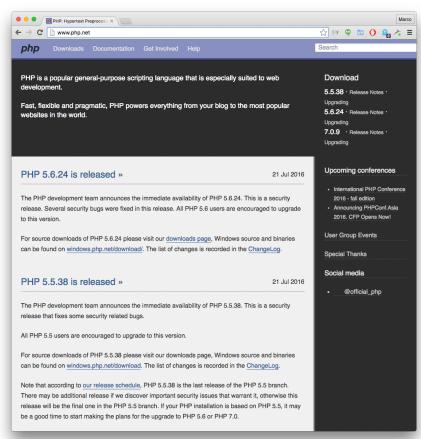

Put it All Together (cont'd)

```
//Display a table
echo "";
While ($row = mysql fetch array($result)) {
 echo "";
   foreach ($row as $key => $value) {
      echo "$value";
   echo "";
echo "";
mysql close($link);
?>
</body></html>
```

The Results

ID	Time	New	Rain Total Rain
382422089522600	2007-08-13 03:00:00	0.19	11.76

www.php.net

www.php.net is the main destination for PHP. The site includes all source/binary releases of PHP plus tutorials and discussion groups. Another excellent site for PHP is www.phphelp.com.
